COMPORTAMENTO DAS FÓRMULAS EXPERIMENTAIS RHODIA FORA DA ESTAÇÃO DE PAULÍNIA

INTRODUÇÃO

Nos juntamos neste relatório os resultados e as observações obtidos pelas fórmulas experimentais de Milho Rhodia em ensaios fora da estação de Paulínia na campanha 89-90 .

Dois tipos de ensaios foram instalados :

- Em estações (ou locais similares a uma estação) que colaboram com a Rhodia . Neste caso, o dispositivo experimental foi de blocos casualizados de 20 tratamentos com 4 repetições . O tratamento número 20 foi reservado para a testemunha local, escolhida pelo responsável técnico de cada local (em geral a melhor ou mais difundida variedade da região).

* Estações experimentais da COTIA de Ponta Grossa (PR), Londrina (PR), Presidente Prudente (SP), Dourados (MS), São Gotardo (MG) e Barreiras (BA) .

* Estação central da Dinamilho em Jardinópolis (SP) .

* Fazenda Itamarati Norte em Tangará da Serra (MT) .

* Fazenda Progresso em São Lucas do Rio Verde (MT) .

* Fazenda Rio Dourado em Montes Claros (MG) .

- Em condições reais de cultivo em fazendas ou sítios, os ensaios foram tratados exatamente como as culturas do fazendeiro (preparação do solo, adubação, tratamentos fitossanitários, densidade de plantio, etc.) . O dispositivo neste caso foi de blocos casualizados de 20 tratamentos com 2 repetições . A parcela elementar foi aproximadamente de 20 m² dependendo da densidade escolhida pelo próprio fazendeiro. Neste tipo de ensaio, o tratamento 20 foi também reservado para a testemunha escolhida pelo fazendeiro .

* Batatais (SP) 2 ensaios com 2 datas de plantio diferentes.

* Franca (SP)

* Ituverava (SP)

* São José de Rio Preto (SP)

- * Uberlândia (MG) 3 ensaios em 3 fazendas
- * Monte Carmelo (MG)
- * Irai de Minas (MG)
- * Arapongas (PR)
- * Rolândia (PR)
- * Ibiporã (PR)
- * Guaxupé (MG)
- * Muzambinho (MG) 2 ensaios

Todos os resultados que tinham chegado até nós na data deste relatório estão em anexos.

ANÁLISE DOS RESULTADOS

Este tipo de experimentação multilocal representa o último estágio de teste dos híbridos experimentais, depois de vários anos de testes preliminares e de confirmação em estação. Nós consideramos que só nestes ensaios multilocais e em condições reais de cultivo, pode ser comprovado o valor e o interesse real das fórmulas.

1. ENSAIOS EM CONDIÇÃO DE ESTAÇÃO

Foi difícil juntar resultados de estação que não tem a mesma técnica experimental. Em alguns casos, tivemos que ajustar os dados para que fosse possível uma análise global. As tabelas de síntese (tab.1 et tab.2) destes dados estão ainda incompletas devido a não recebimento dos dados de algumas estações. Apesar deste fato, nós fizemos uma rápida análise global que mostra:

- Várias fórmulas experimentais se posicionam na mesma faixa de rendimento médio que a média das testemunhas: IR 30, IR 31, TX 1004, TX 1001, TX 1027, SW 1026, TX 1009, TX 1013 e SW 1024.

- Em 5 estações, algumas destas fórmulas superaram nitidamente a testemunha local (A testemunha BR 201 em 3 estações da COTIA foi em média superada por várias fórmulas) enquanto em 2 estações, a testemunha se mostrou superior (G500 em Dourados e DINA 50 em Jardinópolis).

- Em termos de arquitetura e de resistência ao acamamento e quebra, não se evidenciaram defeitos eliminatórios nas fórmulas em comparação às testemunhas .

- A forte pressão de *Helminthosporium turcicum* mostrou a sensibilidade de IR 21 e de IR 22 que por isto, foram eliminadas .

2. ENSAIOS EM CONDIÇÕES REAIS DE CULTIVO

Responsáveis pelo plantio e a colheita, nós obtivemos dados completos e totalmente homogêneos e por isto, pudemos comparar com mais precisão as fórmulas . As tabelas de síntese dos ensaios em condições reais de cultivo (tab.3, tab.4, tab.5, tab.6) mostram o excelente desempenho das fórmulas em geral . Classificamos as fórmulas pela ordem média obtida em cada ensaio porque pensamos que o fator estabilidade de rendimento, ou seja a capacidade de uma fórmula para conseguir uma boa colocação nas mais variadas condições, é um índice muito importante na decisão de difundir uma fórmula . Calculamos as regressões dos rendimentos próprios das fórmulas sobre os rendimentos médios de cada ensaio . A tradução gráfica destas regressões, que corresponde a um "índice de estabilidade", aparece na figura 1 . Estes gráficos podem ser lidos da seguinte forma : quanto mais a reta de regressão é inclinada, menos a variedade é estável, ou seja mais ela responde às técnicas agronômicas e aos insumos .

Outros ensaios em condições reais de cultivo foram plantados em várias fazendas, mas com um protocolo diferente. A tabela 7 resume as observações destes ensaios .

As conclusões desta experimentação são as seguintes:

- Em média, das 19 fórmulas testadas, 15 igualam ou superam a testemunha de cada local . 5 fórmulas mostram um ganho médio sobre a testemunha de cerca de 20 % .

- A estabilidade de rendimento, para ser interessante, deve estar ligada à alta potencialidade . 4 fórmulas mostram alta potencialidade e estabilidade :

fórmula	constante	coeficiente
SW 1026	6,16	0,99
IR 31	6,02	1,07
TX 1027	7,74	0,96
SW 1024	1,87	1,07

- IR 30, com um coeficiente de regressão excepcional (1,32), mostra uma forte capacidade de resposta à tecnificação do cultivo . IR 30 então é mais uma variedade a ser difundida nas áreas menos aleatórias e mais tecnificadas.

- TX 1006 é ao contrario com um coeficiente muito baixo (0,71) mais com uma constante muito alta (14,57) . Isso indica uma estabilidade fora do comun e então uma vocação para as áreas menos tecnificadas e mais aleatórias .

- Essas conclusões são confirmadas por um ensaio multilocal amplo que testou vários destes materiais em mais de 30 locais das áreas tropicais do mundo . As primeiras análises globais dos ensaios em estações são um pouco contraditórias, particularmente para IR 30 e IR 31 . Vamos esperar a totalidade dos dados chegar para uma conclusão definitiva .
